

HMM PoS

October 23, 2023

1 Part A: Parts of Speech Tagging using Hidden Markov Model and Viterbi Algorithm on Hindi Dataset (Total: 40 Points out of 100)

For this assignment, we will implement the Viterbi Decoder using the Forward Algorithm of Hidden Markov Model as explained in class.

Then, we will create an HMM-based PoS Tagger for Hindi language using the annotated Tagset in `nlk.indian`

You need to first implement the missing code in `hmm.py`, then run the cells here to get the points

```
[ ]: from tqdm.autonotebook import tqdm

[ ]: # This is so that you don't have to restart the kernel everytime you edit hmm.py

%load_ext autoreload
%autoreload 2
```

The autoreload extension is already loaded. To reload it, use:

```
%reload_ext autoreload
```

```
[ ]: from hmm import *

[ ]: words, tags, observation_dict, state_dict, \
      get_observation_ids(sentence_words, observation_dict), \
      get_state_ids(sentence_tags, state_dict)

words, tags, observation_dict, state_ditch = get_hindi_dataset()
```

```

1.1 1st-Order Hidden Markov Model Class:

The hidden markov model class would have the following attributes:

1. initial state log-probs vector (π)
2. state transition log-prob matrix (A)
3. observation log-prob matrix (B)

The following methods:

1. fit method to count the probabilities of the training set
2. path probability
3. viterbi decoding algorithm

```

function VITERBI(observations of len T, state-graph of len N) returns best-path, path-prob

create a path probability matrix viterbi[N,T]
for each state s from 1 to N do                                ; initialization step
    viterbi[s,1] ←  $\pi_s * b_s(o_1)$ 
    backpointer[s,1] ← 0
for each time step t from 2 to T do                                ; recursion step
    for each state s from 1 to N do
        viterbi[s,t] ←  $\max_{s'=1}^N viterbi[s',t-1] * a_{s',s} * b_s(o_t)$ 
        backpointer[s,t] ←  $\operatorname{argmax}_{s'=1}^N viterbi[s',t-1] * a_{s',s} * b_s(o_t)$ 
    bestpathprob ←  $\max_{s=1}^N viterbi[s,T]$                                 ; termination step
    bestpathpointer ←  $\operatorname{argmax}_{s=1}^N viterbi[s,T]$                         ; termination step
    bestpath ← the path starting at state bestpathpointer, that follows backpointer[] to states back in time
return bestpath, bestpathprob

```

Figure A.9 Viterbi algorithm for finding optimal sequence of hidden states. Given an observation sequence and an HMM $\lambda = (A, B)$, the algorithm returns the state path through the HMM that assigns maximum likelihood to the observation sequence.

1.2 Task 1: Testing the HMM (20 Points)

```
[ ]: ### DO NOT EDIT ###

# 5 points for the fit test case
# 15 points for the decode test case

# run the funtion that tests the HMM with synthetic parameters!
run_tests()
```

Testing the fit function of the HMM
All Test Cases Passed!
Testing the decode function of the HMM

All Test Cases Passed!
Yay! You have a working HMM. Now try creating a pos-tagger using this class.

1.3 Task 2: PoS Tagging on Hindi Tagset (20 Points)

For this assignment, we will use the Hindi Tagged Dataset available with nltk.indian

Helper methods to load the dataset is provided in hmm.py

Please go through the functions and explore the dataset

Report the Accuracy for the Dev and Test Sets. You should get something between 65-85%

```
[ ]: words, tags, observation_dict, state_dict, all_observation_ids, all_state_ids = ↳
      get_hindi_dataset()

# we need to add the id for unknown word (<unk>) in our observations vocab
UNK_TOKEN = '<unk>'

observation_dict[UNK_TOKEN] = len(observation_dict)
print("id of the <unk> token:", observation_dict[UNK_TOKEN])
```

id of the <unk> token: 2186

```
[ ]: print("No. of unique words in the corpus:", len(observation_dict))
print("No. of tags in the corpus", len(state_dict))
```

No. of unique words in the corpus: 2187
No. of tags in the corpus 26

```
